

Infix Notation

- ✱ Each binary operator is placed between its operands.
- ✱ Each unary operator precedes its operand.

$$-2 + 3 * 5 \quad \longleftrightarrow \quad (-2) + (3 * 5)$$

Postfix expressions are easy to evaluate:

- ✱ no subexpressions
- ✱ precedence among operators already accounted for

But this is not the case for infix expressions!

e.g. $9 + (2 - 3) * 8$

Infix Expression Evaluation

Two approaches to evaluate an infix expression:

✦ Use two stacks within one scan.

✓ ✦ Convert to equivalent postfix expression and then call the postfix evaluator.

Operator Associativity

Left associative: +, −, *, /, %

$$2 + 3 + 4 - 8 \quad \longleftrightarrow \quad ((2 + 3) + 4) - 8$$

$$8 / 4 * 3 \quad \longleftrightarrow \quad (8 / 4) * 3$$

Right associative: ^

$$2^7^6 + (3 - 2 * 4) \% 5$$

$$2^{(7^6)} + ((3 - (2 * 4)) \% 5)$$

Operator Precedence

$() > ^ > * = \% = / > + = -$

$12 + 23 * 4 ^ (3 - 7 / 11 ^ 2) \% 25$

$12 + \left(\left(23 * \left(4 ^ \left(3 - \left(7 / (11 ^ 2) \right) \right) \right) \right) \% 25 \right)$

Rank of Expression

Evaluates an infix expression based on *rank*.

1	for any operand
-1	for +, −, *, /, %, ^
0	for (,)

Cumulative rank: sum of the ranks of individual terms.

$$2 \wedge 7 \wedge 6 + (3 - 2 * 4) \% 5$$

cumulative
rank: 1 0 1 0 1 0 0 1 0 1 0 1 1 0 1

Necessary Condition for Correctness

The cumulative rank after each symbol is always 0 or 1, and for the entire expression must be 1.

(exactly one more operand than operator)

Invalid expression if condition is not satisfied.

2 4 + 3

However, the condition is not sufficient, i.e., satisfying the condition does not imply the correctness.

(4 + 3

8)) % 2

How to further check the correctness?

Convert it to postfix
and evaluate!

4 (+) 3 \Rightarrow 4 + 3 error!

Infix-to-Postfix Conversion

During the scan of an expression:

- ✱ Write an operand immediately to the output string.
- ✱ No need to maintain an operand stack.

Operator stack

- ✱ Stores operators and left parentheses as soon as they appear.
- ✱ Manages the order of precedence and associativity of operators.
- ✱ Handles subexpressions.

Example 1

The stack temporally stores operators awaiting their right operand.

a + b * c

↑ ↑ ↑ ↑ ↑

* has higher priority than +
⇒ add to the stack

Operator
stack:

Postfix
string:

Example 2

Use the stack to handle operators with same or lower precedence.

a * b / c + d

↑ ↑ ↑ ↑ ↑

* has the same priority as /
⇒ pop * and write it to the postfix string
before adding / to the stack.

Operator
stack:

+

Postfix
string:

a	b	*	c	/	d	+
---	---	---	---	---	---	---

/ has higher priority than +

Example 3

Use precedence values to handle \wedge (right associative).

input precedence 4 when \wedge is the input.

stack precedence 3 when \wedge resides on the stack.

a \wedge b \wedge c

↑ ↑ ↑

Operator
stack:

Postfix
string:

2nd \wedge has precedence 4 but 1st \wedge has only 3

⇒ 2nd \wedge goes to operator stack (so it will be popped before 1st \wedge)

Example 4

Two precedence values for left parenthesis (:

input precedence 5 which is higher than that of any operator.

(all operators on the stack must remain because a new subexpression begins.)

a * (b + c)

Operator
stack:

Postfix
string:

(has precedence 5 \Rightarrow
it goes to the operator stack.

(now has precedence -1 \Rightarrow
it stays on the operator stack.

pop all operators from the stack
until (is at the top.

) cancels (at the top.

Input and Stack Precedence

Symbol	Input Precedence	Stack Precedence	Rank
+ −	1	1	-1
* / %	2	2	-1
^	4	3	-1
(5	-1	0
)	0	0	0

(is also right associative with higher input precedence 5 than stack precedence -1. E.g., $((2 + 3) - 4) * 5$.

2 3 + 4 -

 $2 \quad 3 \quad + \quad 4 \quad -$

* [2]

$$2 \ 3 + 4 - 5$$
$$2 \ 3 + 4 - 5 *$$

Rules for Evaluation

- ★ Check the cumulative rank after each symbol (must be in the range from 0 to 1).
- ★ Write the input to the postfix string if it is an operand.
- ★ Upon input of an operator or a (, compare its **input precedence** with the **stack precedence** of the top operator on the stack.
- ★ If the input is), pop all operators from the stack until (and write them to the postfix string. Pop (.
- ★ At the end of the infix expression, pop all remaining operators from the stack and write them to the postfix string.

$$3 * (4 - 2^5) + 6$$

The InfixExpression Class

outputHigherOrEqual()

- ✱ Pops the operator stack as long as the operator on the top of the stack has a stack precedence **higher than or equal to** the input precedence of the current operator *op*.
- ✱ Writes the popped operators to the postfix string.
- ✱ If *op* is a ')', and the top of the stack is a '(', also pops '(' from the stack but does not write it to the postfix.

Conversion to Postfix

`postfix()` scans an infix string and does the following:

- ✱ Skips a whitespace character.
- ✱ Writes an operand to the postfix string.
- ✱ Calls `outputHigherOrEqual()` with an operator.
- ✱ Also calls `outputHigherOrEqual()` when the input is `)`.
- ✱ Terminates at the end of the expression or if an error occurs.

Running Time of Conversion

Suppose the infix string has n operators and operands:

- ✱ A call to `outputHigherOrEqual()` may pop $O(n)$ operators off the stack.

$1 + 2^3 4^{\dots} 100$

- ✱ $O(n)$ such calls.

$O(n)$ -time infix-to-postfix conversion.

Total time $O(n^2)$?

Not tight. Let's count write, push, and pop operations.

- ✱ Every operator or operand that's not '(' or ')' is written to the postfix string. $O(n)$ writes.
- ✱ Every operator that is not ')' gets pushed onto the stack. $O(n)$ pushes.
- ✱ $\#pops \leq \#pushes$. So there are $O(n)$ pops in total.

Reporting Errors

`postfix()` also keeps track of the cumulative rank and catches five types of error :

- ✱ “Operator expected” if the rank goes above 1;
- ✱ “Operand expected” if the rank goes below 0;
- ✱ “Missing ‘(’” if a scanned ‘)’ in an empty stack without popping any ‘(’ out;
- ✱ “Missing ‘)’” if a ‘(’ is left unmatched on the stack at the end of the scan;
- ✱ “Invalid character” if the character is not a digit or operator.
